

Notes from Multistate weed emergence project, Jan 12, 2021, via Zoom.

Attending, Toni DiTommaso, Rich Smith, Lynn Sosnoskie, Thierry Besancon, Mark Van Gessel, John Wallace, Carolyn Lowry, Vijay Singh, Ruth Magnum, Kreshnik Bejleri, Caio Brunharo, Mohsen Mesgaren.

### **Action Items & Decisions:**

Please return old sensors and data loggers to Ruth Magnum:

USDA/ARS/SASL  
Ruth Mangum  
Building 001 Room 011  
10300 Baltimore Ave  
Beltsville, MD 20705

Carri will look for additional researchers; please do email any suggestions for that as I didn't catch the names in the meeting.

Carri will send out new sensors in February.

Carolyn, Caio, Vijay, and anyone else interested in helping plan greenhouse experiments will meet to support this work and potentially spin off related cold temperature/dormancy work. Carri will set up that meeting up shortly.

If seeding in spring, get those seeds out at least a month ahead of first emergence.

Make sure you catch the first emergence of our target weeds, even if it's before tillage.

It's OK to collect related species, but try to catch as many of our target species as possible. Many of our collaborators are collecting additional species.

Several researchers are both interested in galinsoga; if we would like to set up a study to mimic Dr. Sweet's work from midcentury to look for changes, let's set up a time to discuss that or do so over email.

### **General Discussion Notes**

Kresh/Ruth/Steve collected data in 2020 in MD. They collected data on naturally emerging pigweed, ragweed, ivy-leaf morningglory, and foxtail. During peak emergence they applied glyphosate after counting; as emergence tapered, they hand pulled. They scaled their plot size from 1/4m to 1 m as emergence varied.

Carolyn Lowry has an idea about cold temperatures and dormancy. Looking for weeds from collaborators to try this, and collect pilot data for an AFRI.

Caio is open to doing a temperature/emergence germination trial to help us pin down base temperatures. He has six chambers available.

Would it add to look at germination of samples in growth chambers? Absolutely, especially if you can do it across multiple temperature – 6-8 temperatures – and then incorporate that into the model. If you can do hydrothermal even better, but it's a huge amount of work and very fiddly.

Vijay is also willing to do some germination trials.

Some people seeding, some counting natural emergence. Some seeding in fall, others seeding in spring. If seeding in spring, get those seeds out at least a month ahead of first emergence.

Make sure you catch the first emergence of our target weeds, even if it's before tillage.

It's OK to collect related species, but try to catch as many of our target species as possible. Many of our collaborators are collecting additional species.

NJ collected hairy galinsoga for NY; we observed that they are emerging the same season as it's dropped. Dr. Sweet did some great accounts on galinsoga; one thing they noted was that in a good year, you could get three generations of galinsoga in one year. Mark's been asking us to do a climate change paper, to compare with Dr. Sweet's data from the 1950s and 1960s. That's the equivalent of our project; multiple stations in the NE. <https://www.newss.org/publications/> If it's germinating that rapidly, weekly germinating may not be adequate.

From Lynn: Toni, Galinsoga is a real problem in CNY and WNY, so if there is more that can be done, Elizabeth Buck may be interested in assisting.

**Non-Technical Summary**

Unlike crops, which have been selected for uniform emergence, weed species have evolved variability in timing of their emergence; even seeds maturing on the same plant may germinate at different times. This "bet-hedging" strategy, with which a weed avoids putting all its "seed in one basket" of emergence timing, enables weeds to escape control measures that are applied at the "wrong" time. Post-emergence management carried out too early, i.e. before most problem weeds have emerged, will yield low returns for the effort, investment, and ecological cost of the management (herbicide off-target effects, soil compaction, etc.), as weed seeds that have yet to germinate are often unaffected. Providing seedling emergence information so that farmers can effectively time their weed management operations can increase efficacy of control, reduce labor costs, and minimize any negative environmental impacts (e.g. reduce the likelihood that repeat applications of an herbicide or cultivation may be required for late germinating/emerging weeds). There is, therefore, an urgent need for the development of time-specific weed management tools to help address the frequently asked, yet to be answered, question of when is the "right" time to control weeds?

Weed seedling emergence is a complex process regulated by a multitude of internal (e.g. species-specific parameters such as base temperature, base water potential) and environmental (e.g. soil temperature and moisture) factors. A range of modeling approaches, varying from simple empirical to advanced mechanistic models, have therefore been adopted to quantify the extent and time of emergence for a significant number of weeds. These can be used to produce weed management decision support tools, which enable farmers to determine the percent emergence of a specific weed species by a given date, taking into account the weather, management actions, and field conditions to that point. Populations of weeds respond differently in different regions to climate and habitat, requiring that emergence models be modified for a particular region. No weed management decision support tool exists for the Northeastern region of the United States, despite recent advances in our understanding of regional weed emergence patterns and developments in fine-scale weather prediction and soil moisture modeling. Data exist to create a weed forecasting product similar to those available for insect and disease threats to Northeastern agriculture, which would enable farmers to approach weed management with more precision and planning. In the past decade, decision support tools have been developed to help farmers manage weeds effectively in the Midwestern United States and Europe; these would serve as a road map for the Northeastern decision support tool. Recent advancements in climate and weather models and computational power have generated detailed weather data that are available to the general public free of charge. In the Northeast, daily weather data are now available on a 4 × 4 km grid across the region using the Applied Climate Information System (ACIS) Web Services (DeGaetano et al. 2014). These databases provide an unprecedented opportunity to estimate parameters directly relevant to seedling emergence such as growing degree day and hydrothermal time, from soil temperature and moisture data at very fine spatial resolution.

The **overarching goal of this project** is to work collaboratively across the northeast region to optimize farmers' ability to manage weeds in agricultural systems, in the face of challenges posed from a changing climate and increased prevalence of herbicide resistant weeds.

## Progress Report

Accession No. 1018540

Project No. NYC-125838

Multistate No. NE1838

In this proposal, our goal is to develop and validate a user-friendly, online decision support tool for the real time prediction of weed emergence in the northeastern US. The decision support tool takes GPS location, soil type, tillage, crop data, and accesses weather history to provide percent emergence of the farmer's problem weeds at that location.

**Accomplishments****Major goals of the project**

(1)

Link Northeastern weed emergence timing data to existing weed emergence models and modern weather prediction models to create an online tool for farmers that will help them plan their weed management for optimal weed control. This tool will include three weeds that are problematic across the region: common lambsquarters (*Chenopodium album*), redroot pigweed (*Amaranthus retroflexus*) and large crabgrass (*Digitaria sanguinalis*). Common ragweed (*Ambrosia artemisiifolia*) will also be included in the northern portion of the Northeast and morningglory species (*Ipomoea* spp.) in the southern portion of the region. Individual participating states may also include one additional species of particular interest to their state.

(2)

Collect weed emergence data across the region to validate and refine the existing weed emergence models to fit Northeastern data, and refine the decision support tool through testing by select farmers and extension staff.

**What was accomplished under these goals?**

From October of 2019 through February of 2020, we planned and executed our first year of data collection, compiled the resulting data, and updated our emergence models with assistance from all of our partners. Mohsen Mesgaren of UC Davis and Carlos Santos of the University of Seville were key to this first years' work, especially in the model development area. Our progress were presented by Caroline Marschner at the 2020 NEPPSC conference in Philadelphia, PA, and we held two winter collaborator meetings to update our research plans and organize the upcoming field season.

As our first season of data were collected, it became clear that we needed more reliable in-field data collection for soil moisture and temperature. We submitted a revision to our budget to purchase field sensor equipment for this project, which was accepted, and received the sensors in March of 2020 for the 2020 field season.

In March 2020, the novel coronavirus pandemic and the resulting lockdowns at universities across the US precluded most of our partners, including our own lab, from initiating our 2020 field season in time to capture weed seedling emergence for our target species (March-April emergence initiation, depending on the state). In order to retain the ability to collect the three years of data necessary for this project, we stopped all spending and work on this project and received a one-year no cost extension, resulting in a grant end date of September 2022.

**What opportunities for training and professional development has the project provided?**

Our visiting scholar, Carlos Santos of the University of Seville, had the opportunity for substantial training in weed seedling emergence modeling with Mohsen Mesgaren of UC Davis, one of our multistate collaborators.

**How have the results been disseminated to communities of interest?**

Our progress was presented by Caroline Marschner at the 2020 NEPPSC conference in Philadelphia, PA, and to the Cornell University Integrated Pest Management course through the lens of weed emergence and climate change.

**What do you plan to do during the next reporting period to accomplish the goals?**

We plan to conduct our winter meetings, send the new sensor systems to our collaborators, and conduct our second field season this year (2021). We will continue to work on the review paper for the project. The next round of revisions for the model will fall in the 2022 fiscal year, as will development of the public-facing prediction model.

{NO DATA ENTERED}

## Target Audience

We educated undergraduate students in the Cornell Integrated Pest Management course about the changes expected with climate change on weed seedling emergence and the complexities of modeling and predicting weed emergence. We reached the weed science community with an update on our project and the changes to the models that our data suggested from the first year of data collection.

## Other Products

## Product Type

Data and Research Material

## Description

Collated and analyzed the data produced in the first field season for this project, creating our first pool of data to support the model and prediction tool.

## Product Type

Models

## Description

Updated our preliminary models with the first year of data, experimenting with several different model types and testing them against our data.

## Changes/Problems

We determined that sensor systems for soil moisture and temperature were needed to develop a more accurate model for the predictive tool. As a result, we submitted and were approved for a budget modification to reallocate funds to the purchase of the sensor systems.

The coronavirus pandemic halted this project, and all but one of our field sites collected no data in 2020. We paused both
